# 1 Introduction

The object is to use reinforcement learning to solve the following scenario: a customer arrives with a number of features, we want to promote the customer with a proper price, such that he is most likely to purchase our product, and we also have the highest profit and a better portfolio.

We can consider this scenario as markov decision process, with the current state being the current customer features and current portfolio. At each time step, the agent promote a price according to the current customer features and the current portfolio, after that the customer resopnse to the action. The reward is then given besed on the customer response and the portfolio. Then the portfolio updates and a new customer arrives.

# 2 Reinforcement Learning

The reinforcement learning method we want to use is based on the Markov decision process (MDP), as illustrated below:

However, in RL, the agent is not told which actions to take, but instead must discover which actions yield the most reward by trying them. Our goal at each time step is to find a policy  $\pi$  to maximize the expected reward alonge the process afterwards, which is given by the value function

$$V(s) = \mathbb{E}\left[\sum_{i=0}^{\infty} \gamma^{i} R_{t+i+1} \mid S_{t} = s\right]$$

To achieve this, we need to evaluate the current policy, and improve it accordingly.

## 2.1 Policy Evaluation

We want to evaluate the value function under a given policy  $\pi$ . According to Bellman equation,

$$v_{\pi}(s) = \mathbb{E}_{\pi} \left[ R_{t+1} + \gamma v_{\pi}(S_{t+1}) \mid S_t = s \right]$$

We can use it to iteratively compute  $v_{\pi}$ . The iteratively update is

$$v_{k+1}(s) = \mathbb{E}_{\pi} \left[ R_{t+1} + \gamma v_k(S_{t+1}) \mid S_t = s \right]$$

which is proven that it will converge to the true value given any initial value function.

#### 2.2 Policy Improvement

Now we have the evaluated value function for the policy, we want to improve it accordingly. To do this, we introduce the q-function under policy  $\pi$ 

$$q_{\pi}(s, a) = \mathbb{E}[R_{t+1} + \gamma v_{\pi}(S_{t+1}) \mid S_t = s, A_t = a]$$

The policy improvement theorem says that, let  $\pi$  and  $\pi'$  be any pair of policy, for all s we have

$$q_{\pi}(s, \pi'(s)) \ge v_{\pi}(s) \Rightarrow v_{\pi'}(s) \ge v_{\pi}(s)$$

Now we can improve the policy by

$$\pi'(s) = \operatorname*{argmax}_{a} q_{\pi}(s, a)$$

for all s.

#### 2.3 Policy Iteration

By iteratively applying policy evaluation and policy improvement, we can obtain a sequence of monotonically improving policies and value functions:

$$\pi_0 \xrightarrow{E} v_{\pi_0} \xrightarrow{I} \pi_1 \xrightarrow{E} v_{\pi_1} \xrightarrow{I} \dots \xrightarrow{I} \pi_* \xrightarrow{E} v_*$$

where  $\stackrel{E}{\longrightarrow}$  denotes a policy evaluation and  $\stackrel{I}{\longrightarrow}$  denotes a policy improvement. This way of finding an optimal policy is called policy iteration.

#### 2.4 Value Iteration

One drawback to policy iteration is that each of its iterations involves policy evaluation, which itself is a protracted iterative computation requiring multiple sweeps through the state set.

We now truncate the policy evaluation such that it is stopped after just one sweep (one update of each state):

$$v_{k+1}(s) = \max_{a} q(s, a)$$
  
=  $\max_{a} \mathbb{E} [R_{t+1} + \gamma v_k(S_{t+1}) \mid S_t = s, A_t = a]$ 

We keep iterate until v converges (to  $v_*$ ), then we record the last policy  $\pi(s) = \underset{a}{\operatorname{argmax}} q(s, a)$ .

# 2.5 Generalized Policy Iteration

As long as both processes, policy evaluation and policy improvement, continue to update all states, the ultimate result is typically the same — converge to the optimal value function and an optimal policy.

Generalized policy iteration (GPI) is used to refer to the general idea of letting policy evaluation and policy improvement interact, independent of the granularity of the two processes (instead of letting each complete before the other begins).

### 2.6 Temporal-Difference Learning

When we don't have the complete model of the environment, we need to estimate the value function from only experience. There are two methods to do so: Monte Carlo Methods and Temporal-Difference. We will use Temporal-Difference method in this project.

To estimate  $v_{\pi}(S_t)$  using only the experience, we take the average on all experienced trajectory' values. Temporal-Difference method uses  $G_i = [R_{t+1}]_i + \gamma [v_{\pi}(S_{t+1})]_i$  to estimate the value of the *i*th trajectory starting at  $S_t$ , with  $v_{\pi}$  being the estimated value function at the *i*th time  $S_t$  is visitied, which can be initialized to anything at start. Now we have the incremental formula to update our value function:

$$[v_{\pi}(S_t)]_{k+1} = \frac{1}{k} \sum_{i=1}^k G_i$$

$$= \frac{1}{k} \left( G_k + \sum_{i=1}^{k-1} G_i \right)$$

$$= \frac{1}{k} (G_k + (k-1)[v_{\pi}(S_t)]_k)$$

$$= [v_{\pi}(S_t)]_k + \frac{1}{k} (G_k - [v_{\pi}(S_t)]_k)$$

$$= [v_{\pi}(S_t)]_k + \frac{1}{k} ([R_{t+1}]_k + \gamma [v_{\pi}(S_{t+1})]_k - [v_{\pi}(S_t)]_k)$$

To simplify:

$$v_{\pi}(S_t) \longleftarrow v_{\pi}(S_t) + \alpha[R_{t+1} + \gamma v_{\pi}(S_{t+1}) - v_{\pi}(S_t)]$$

with  $\alpha$  being the stepsize. And this also applies to the q function:

$$q_{\pi}(S_t, A_t) \longleftarrow q_{\pi}(S_t, A_t) + \alpha[R_{t+1} + \gamma q_{\pi}(S_{t+1}, A_{t+1}) - q_{\pi}(S_t, A_t)]$$

## 2.7 Policy Gradient Methods

When the state space is arbitrarily large, we cannot find an optimal policy or the optimal value function given the limited resources and time. Instead of keeping track of the value and the action(s) to select for each state (tabular methods), we can use parameterized functions, for example, artificial neural networks (ANNs), to approximate the value function and the policy function.

Previously methods learned the values of actions and then select actions based on their estimated action values (q function). Now we consider methods that instead learn a parameterized policy that select actions without consulting a value function. A value function may still be used to learn the policy parameter, but is not required for action selection.

We use  $\boldsymbol{\theta}$  and  $\boldsymbol{w}$  to denotes the policy's parameter vector and value function's weight vector, respectively. Then we have our policy  $\pi\left(a\mid s,\boldsymbol{\theta}\right)=\Pr\left\{A_t=a\mid S_t=s,\boldsymbol{\theta_t}=\boldsymbol{\theta}\right\}$  and value function  $v_{\pi}(s,\boldsymbol{w})$ . We also define the scalar performance measure (objective) to be

$$J(\boldsymbol{\theta}) = \begin{cases} v_{\pi_{\boldsymbol{\theta}}}(s_0); & \text{episodic case} \\ \lim_{t \to \infty} \mathbb{E}\left[R_t \mid S_0, A_{0:t-1} \sim \pi\right]; & \text{continuing case} \end{cases}$$

Policy gradient methods seeks to maximize this performance measure, so their updates approximate gradient ascent in J:

$$\theta_{t+1} = \theta_t + \alpha \widehat{\nabla J(\theta_t)}$$

where  $\nabla J(\widehat{\boldsymbol{\theta}_t})$  is a stochastic estimate whose expection approximates the gradient of the performance measure w.r.t  $\boldsymbol{\theta}_t$ .

### 2.7.1 The Policy Gradient Theorem

The policy gradient theorem says

$$\nabla J(\boldsymbol{\theta}) \propto \sum_{s} \mu(s) \sum_{a} q_{\pi}(s, a) \nabla \pi \left(a|s, \boldsymbol{\theta}\right)$$

where  $\mu$  is the stationary distribution of the state. Thus we can derive

$$\nabla J(\boldsymbol{\theta}) \propto \sum_{s} \mu(s) \sum_{a} q_{\pi}(s, a) \nabla \pi \left( a | s, \boldsymbol{\theta} \right)$$

$$= \mathbb{E}_{\pi} \left[ \sum_{a} q_{\pi}(S_{t}, a) \nabla \pi \left( a | S_{t}, \boldsymbol{\theta} \right) \right]$$

$$= \mathbb{E}_{\pi} \left[ \sum_{a} \pi \left( a | S_{t}, \boldsymbol{\theta} \right) q_{\pi}(S_{t}, a) \frac{\nabla \pi \left( a | S_{t}, \boldsymbol{\theta} \right)}{\pi \left( a | S_{t}, \boldsymbol{\theta} \right)} \right]$$

$$= \mathbb{E}_{\pi} \left[ q_{\pi}(S_{t}, A_{t}) \frac{\nabla \pi \left( A_{t} | S_{t}, \boldsymbol{\theta} \right)}{\pi \left( A_{t} | S_{t}, \boldsymbol{\theta} \right)} \right]$$

The policy gradient theorem can be generalized to include a comparison of the action value to an arbitrary baseline b(s):

$$\nabla J(\boldsymbol{\theta}) \propto \sum_{s} \mu(s) \sum_{a} \left( q_{\pi}(s, a) - b(s) \right) \nabla \pi \left( a | s, \boldsymbol{\theta} \right)$$

with the same derivation we have

$$\nabla J(\boldsymbol{\theta}) \propto \mathbb{E}_{\pi} \left[ \left( q_{\pi}(S_t, A_t) - b(S_t) \right) \frac{\nabla \pi \left( A_t | S_t, \boldsymbol{\theta} \right)}{\pi \left( A_t | S_t, \boldsymbol{\theta} \right)} \right]$$

One natural choice for baseline is an estimate of the state value,  $\hat{v}(S_t, \boldsymbol{w})$ , where  $\boldsymbol{w}$  is the weight vector to be learned.

#### 2.7.2 Actor-Critic Methods

Recall the TD method, we make use of  $q_{\pi}(s, a) = \mathbb{E}[R_{t+1} + \gamma v_{\pi}(S_{t+1}) \mid S_t = s, A_t = a]$ , by taking one sample estimate, and choosing  $\hat{v}(S_t, \mathbf{w})$  as baseline, we have

$$\nabla J(\boldsymbol{\theta}) \propto \mathbb{E}_{\pi} \left[ \left( R_{t+1} + \gamma \hat{v}(S_{t+1}, \boldsymbol{w}) - \hat{v}(S_t, \boldsymbol{w}) \right) \frac{\nabla \pi \left( A_t | S_t, \boldsymbol{\theta} \right)}{\pi \left( A_t | S_t, \boldsymbol{\theta} \right)} \right]$$

Again, by taking one sample estimate we have the update formula for  $\theta$ :

$$\boldsymbol{\theta}_{t+1} = \boldsymbol{\theta}_t + \alpha_{\boldsymbol{\theta}} \Big( R_{t+1} + \gamma \hat{v}(S_{t+1}, \boldsymbol{w}) - \hat{v}(S_t, \boldsymbol{w}) \Big) \frac{\nabla \pi \left( A_t | S_t, \boldsymbol{\theta}_t \right)}{\pi \left( A_t | S_t, \boldsymbol{\theta}_t \right)}$$
$$= \boldsymbol{\theta}_t + \alpha_{\boldsymbol{\theta}} \delta_t \nabla \ln \pi \left( A_t | S_t, \boldsymbol{\theta}_t \right)$$

As for the weight vector  $\boldsymbol{w}$  for the estimated value function, at each time step t, we want to update it by minimizing the squared error,  $[v_{\pi}(S_t) - \hat{v}(S_t, \boldsymbol{w}_t)]^2$ :

$$\mathbf{w}_{t+1} = \mathbf{w}_t - \alpha_{\mathbf{w}}' \nabla \left[ v_{\pi}(S_t) - \hat{v}(S_t, \mathbf{w}_t) \right]^2$$
$$= \mathbf{w}_t - \alpha_{\mathbf{w}} \left( v_{\pi}(S_t) - \hat{v}(S_t, \mathbf{w}_t) \right) \nabla \hat{v}(S_t, \mathbf{w}_t)$$

where  $v_{\pi}$  is the true value function. Again, since  $v_{\pi}(s) = \mathbb{E}[R_{t+1} + \gamma v_{\pi}(S_{t+1}) \mid S_t = s]$ , we take one sample estimate, which gives us the update formula for  $\boldsymbol{w}$ :

$$\mathbf{w}_{t+1} = \mathbf{w}_t - \alpha_{\mathbf{w}} \Big( R_{t+1} + \gamma \hat{v}(S_{t+1}, \mathbf{w}) - \hat{v}(S_t, \mathbf{w}_t) \Big) \nabla \hat{v}(S_t, \mathbf{w}_t)$$
$$= \mathbf{w}_t - \alpha_{\mathbf{w}} \delta_t \nabla \hat{v}(S_t, \mathbf{w}_t)$$

The actor-critic method is based on the above updates formulas:

#### Algorithm 1 Actor-Critic

```
1: Input: a differentiable policy parameterization \pi(a|s,\theta)
 2: Input: a differentiable state-value function parameterization \hat{v}(s, \boldsymbol{w})
 3: Step sizes \alpha_{\theta} > 0, \alpha_{w} > 0
 4: \theta \leftarrow 0, w \leftarrow 0
 5: loop (for each episode)
            Initialize S (first state of the episode)
 6:
 7:
 8:
            loop (for each time step)
                  A \sim \pi \left( \cdot | S, \boldsymbol{\theta} \right)
 9:
                  Take action A, observe S', R
10:
                  \delta \leftarrow R + \gamma \hat{v}(S', \boldsymbol{w}) - \hat{v}(S, \boldsymbol{w})
11:
                  \boldsymbol{w} \leftarrow \boldsymbol{w} + \alpha_{\boldsymbol{w}} \delta \nabla \hat{v}(S, \boldsymbol{w})
12:
                  \theta \leftarrow \theta + \alpha_{\theta} I \delta \nabla \ln \pi \left( A | S, \theta \right)
13:
                  I \leftarrow \gamma I
14:
                  S \leftarrow S'
15:
            end loop
16:
17: end loop
```

## 3 Build the Environment

The environment does the following things:

- 1. record the current state that can be queried anytime
- 2. when an action, i.e. a price, is given according to the current state, it outputs the reward, and goes to next state

At each time step, the state consists of a randomly generated customer's features and the current portfolio. After the agent performs an action, i.e. promotes a price to the customer, the reward is then computed based on the profit on this customer and the portfolio up to now.

#### 3.1 Customer Features

A customer' features is represented by an array (or vector), denoted by x with 15 entries with each generated randomly from a distribution, including normal distribution, binomial distribution, and so on. For example, a feature vector x is described as below:

gender	age	car cost	miles	brand	random feature 0	random feature 1	
1.0	42.723	94032.096	30086.311	29.264	8.0	68.740	

After a price, denoted by c, is promoted to a customer, the customer will give a resonance, denoted by r, which is 0 if he does not buy the product, and 1 otherwise. And the profit we have for that customer, denoted by pf, can be computed by

$$pf = r * (c - g(x))$$

where g(x) is the cost on that customer.

#### 3.2 Resonse

The resonance is generated by a generalized linear model, whose input is a vector of a customer features vector x appended with a price c, i.e.  $r = glm(x[0], \ldots, x[14], c)$ .

The GLM used in the project is fitted using a randomly generated data set with each observation is a customer's features followed by a price, then followed by a resonance e.g.

		customer feature 0	 customer feature 14	price	resopnse
	1	1.0	 3.278	1109.504	1.0
-	2	0.0	 1.991	665.8	0.0

And its link function is chose to be the logistic function.

#### 3.3 State

The state at start of each time step is the feature vector of the new customer to promote, appended by the portfolio, which is also a data vector consists of the following entries:

• average profit over all customers so far, expect for the new customer at current time step, denoted by avg\_pf (initialized to 0), which is computed by

$$\text{avg-pf}_t = \frac{1}{t} \sum_{i=0}^{t-1} \text{pf}_i, \ t > 0$$

• the portion of the buyers over all customers, expect for the new one, denoted by p (initialized to 0), which is computed by

$$p_t = \frac{1}{t} \sum_{i=0}^{t-1} r_i, \ t > 0$$

• the variance of the portion of buyers in their categories, denoted by var: we divide customers (expect for the new one at current time step) into 4 categories, according to their features, and for each category, we compute the portion of the customers who buy our product, denoted by  $pt_i$  with i = 1, 2, 3, 4, then we compute the variance of the 4 portions:

$$var = Var(pt) = \frac{\sum_{i=1}^{4} (pt_i - \bar{pt})^2}{3}$$

Later we use this to compute reward to make sure the agent will promote to all types of customers instead of only focusing on one type.

Note that  $var \leq 1$ .

In the end, the state s, or  $s_t$  is of the form  $s_t = (x_t[0], \ldots, x_t[14], \text{ avg-pf}_t, p_t, \text{ var}_t)$ 

#### 3.4 Reward

The reward at each time step t, after the price  $c_t$  is promoted to the customer  $x_t$ , denoted by  $R_t$ , is calculated by

$$R_t = \operatorname{pf}_t \left( 1 - h(\operatorname{var}_t) \right)$$

where h is a function that indicates how much we care about the variance, i.e. how important it is to try to promote to customers of all categories. In this project I choose h to be such that  $h(\text{var}) = \sqrt{\text{var}}/2$ .

## 4 Build the model

With the environment well built, we now build the model for our policy and the value function. In this project we use artificial neuro networks (ANNs) as the parameterized policy and value function, each with four linear layers, and with the ReLU function as the activation function. And the input of both function is the state, as illustrated below:

$$S_t \to \underbrace{\begin{bmatrix} \text{Linear} \\ len(S) \to 128 \end{bmatrix}}_{\text{ReLU}} \to \underbrace{\begin{cases} \text{ReLU} \to \text{Linear} \\ 128 \to 256 \end{cases}}_{\text{128} \to 128} \to \underbrace{\begin{cases} \text{ReLU} \to \text{Linear} \\ 256 \to 128 \end{cases}}_{\text{256} \to 128} \to \underbrace{\begin{cases} \text{ReLU} \to \text{Linear} \\ 128 \to 1 \end{cases}}_{\text{128} \to 1} \to v_t$$

$$S_t \to \underbrace{\begin{cases} \text{Linear} \\ len(S) \to 128 \end{cases}}_{\text{ReLU}} \to \underbrace{\begin{cases} \text{ReLU} \to \text{Linear} \\ 128 \to 256 \end{cases}}_{\text{128} \to 256} \to \underbrace{\begin{cases} \text{ReLU} \to \text{Linear} \\ 256 \to 512 \end{cases}}_{\text{256} \to 512} \to \underbrace{\begin{cases} \text{ReLU} \to \text{Linear} \\ 128 \to n(A) \end{cases}}_{\text{128} \to n(A)} \to \underbrace{\begin{cases} \text{ReLU} \to \text{Linear} \\ 128 \to n(A) \end{cases}}_{\text{128} \to n(A)} \to \underbrace{\begin{cases} \text{ReLU} \to \text{Linear} \\ 128 \to n(A) \end{cases}}_{\text{128} \to n(A)} \to \underbrace{\begin{cases} \text{ReLU} \to \text{Linear} \\ 128 \to n(A) \end{cases}}_{\text{128} \to n(A)} \to \underbrace{\begin{cases} \text{ReLU} \to \text{Linear} \\ 128 \to n(A) \end{cases}}_{\text{128} \to n(A)} \to \underbrace{\begin{cases} \text{ReLU} \to \text{Linear} \\ 128 \to n(A) \end{cases}}_{\text{128} \to n(A)} \to \underbrace{\begin{cases} \text{ReLU} \to \text{Linear} \\ 128 \to n(A) \end{cases}}_{\text{128} \to n(A)} \to \underbrace{\begin{cases} \text{ReLU} \to \text{Linear} \\ 128 \to n(A) \end{cases}}_{\text{128} \to n(A)} \to \underbrace{\begin{cases} \text{ReLU} \to \text{Linear} \\ 128 \to n(A) \end{cases}}_{\text{128} \to n(A)} \to \underbrace{\begin{cases} \text{ReLU} \to \text{Linear} \\ 128 \to n(A) \end{cases}}_{\text{128} \to n(A)} \to \underbrace{\begin{cases} \text{ReLU} \to \text{Linear} \\ 128 \to n(A) \end{cases}}_{\text{128} \to n(A)} \to \underbrace{\begin{cases} \text{ReLU} \to \text{Linear} \\ 128 \to n(A) \end{cases}}_{\text{128} \to n(A)} \to \underbrace{\begin{cases} \text{ReLU} \to \text{Linear} \\ 128 \to n(A) \end{cases}}_{\text{128} \to n(A)} \to \underbrace{\begin{cases} \text{ReLU} \to \text{ReLU} \\ 128 \to n(A) \end{cases}}_{\text{128} \to n(A)} \to \underbrace{\begin{cases} \text{ReLU} \to \text{ReLU} \\ 128 \to n(A) \end{cases}}_{\text{128} \to n(A)} \to \underbrace{\begin{cases} \text{ReLU} \to \text{ReLU} \\ 128 \to n(A) \end{cases}}_{\text{128} \to n(A)} \to \underbrace{\begin{cases} \text{ReLU} \to \text{ReLU} \\ 128 \to n(A) \end{cases}}_{\text{128} \to n(A)} \to \underbrace{\begin{cases} \text{ReLU} \to \text{ReLU} \\ 128 \to n(A) \end{cases}}_{\text{128} \to n(A)} \to \underbrace{\begin{cases} \text{ReLU} \to \text{ReLU} \\ 128 \to n(A) \end{cases}}_{\text{128} \to n(A)} \to \underbrace{\begin{cases} \text{ReLU} \to \text{ReLU} \\ 128 \to n(A) \end{cases}}_{\text{128} \to n(A)} \to \underbrace{\begin{cases} \text{ReLU} \to \text{ReLU} \\ 128 \to n(A) \end{cases}}_{\text{128} \to n(A)} \to \underbrace{\begin{cases} \text{ReLU} \to \text{ReLU} \\ 128 \to n(A) \end{cases}}_{\text{128} \to n(A)} \to \underbrace{\begin{cases} \text{ReLU} \to \text{ReLU} \\ 128 \to n(A) \end{cases}}_{\text{128} \to n(A)} \to \underbrace{\begin{cases} \text{ReLU} \to \text{ReLU} \\ 128 \to n(A) \end{cases}}_{\text{128} \to n(A)} \to \underbrace{\begin{cases} \text{ReLU} \to \text{ReLU} \\ 128 \to n(A) \end{cases}}_{\text{128} \to n(A)} \to \underbrace{\begin{cases} \text{ReLU} \to \text{ReLU} \\ 128 \to n(A) \end{cases}}_{\text{128} \to n(A)} \to \underbrace{\begin{cases} \text{ReLU} \to \text{ReLU} \\ 128 \to n(A) \end{cases}}_{\text{128} \to n(A)} \to \underbrace{\begin{cases} \text{ReLU} \to \text{ReLU} \\ 128 \to n(A) \end{cases}}_{\text{128} \to n(A)} \to \underbrace{\begin{cases} \text{ReLU} \to \text{ReLU} \\ 128 \to n(A) \end{cases}}_{\text{128} \to n(A)} \to \underbrace{\begin{cases} \text{ReLU}$$

where len(S) denotes the vector length of the state and n(A) denotes the number of actions.

## 5 RL with Actor-Critic

In this project, we consider the episodic learning procedure, where each episode has finite time steps, N, to be specified as a constant, and we will also reset the environment at the start of each episode. The algorithm below is to use RL, with actor-critic method, and with the help of what we have built in previous sections, to solve the problem:

## Algorithm 2 RL-Actor-Critic-for-financial-problem

```
1: Initialize ANN policy parameterization \pi(c|s, \theta), with any \theta
 2: Initialize ANN state-value function parameterization \hat{v}(s, w) with any w.
 3: Step sizes \alpha_{\theta} > 0, \alpha_{w} > 0
 4: loop (for each episode)
          Reset the environment
 5:
          Generate an x (first customer of the episode)
 6:
          Initialize S (first state of the episode)
 7:
          I \leftarrow 1
 8:
          loop (for each time step, N in total)
 9:
                c \sim \pi\left(\cdot|S, \boldsymbol{\theta}\right)
10:
                Take action c, observe S', R from environment
11:
                \delta \leftarrow R + \gamma \hat{v}(S', \boldsymbol{w}) - \hat{v}(S, \boldsymbol{w})
12:
                \boldsymbol{w} \leftarrow \boldsymbol{w} + \alpha_{\boldsymbol{w}} \delta \nabla \hat{v}(S, \boldsymbol{w})
13:
                \theta \leftarrow \theta + \alpha_{\theta} I \delta \nabla \ln \pi \left( A | S, \theta \right)
14:
                I \leftarrow \gamma I
15:
                S \leftarrow S'
16:
          end loop
17:
18: end loop
```

The following graph illustrates the algorithm:
